## Double Late Write SigmaRAM™

200 MHz–333 MHz  
1.8 V V<sub>DD</sub>  
1.8 V I/O

### Features

- Double Late Write mode, Pipelined Read mode
- JEDEC-standard SigmaRAM™ pinout and package
- 1.8 V +150/–100 mV core power supply
- 1.8 V CMOS Interface
- ZQ controlled user-selectable output drive strength
- Dual Cycle Deselect
- Burst Read and Write option
- Fully coherent read and write pipelines
- Echo Clock outputs track data output drivers
- Byte write operation (9-bit bytes)
- 2 user-programmable chip enable inputs
- IEEE 1149.1 JTAG-compliant Serial Boundary Scan
- 209-bump, 14 mm x 22 mm, 1 mm bump pitch BGA package
- Pin-compatible with future 36Mb, 72Mb, and 144Mb devices

**Bottom View**

### SigmaRAM Family Overview

GS8170DW36/72 SigmaRAMs are built in compliance with the SigmaRAM pinout standard for synchronous SRAMs. They are 18,874,368-bit (18Mb) SRAMs. This family of wide, very low voltage CMOS I/O SRAMs is designed to operate at the speeds needed to implement economical high performance networking systems.

$\Sigma$ RAMs are offered in a number of configurations including Late Write, Double Late Write, and Double Data Rate (DDR). The logical differences between the protocols employed by these RAMs mainly involve various approaches to write cueing and data transfer rates. The  $\Sigma$ RAM™ family standard allows a user to implement the interface protocol best suited to the task at hand.

### Functional Description

Because SigmaRAMs are synchronous devices, address data inputs and read/write control inputs are captured on the rising edge of the input clock. Write cycles are internally self-timed and initiated by the rising edge of the clock input. This feature eliminates complex off-chip write pulse generation required by asynchronous SRAMs and simplifies input signal timing.  $\Sigma$ RAMs support pipelined reads utilizing a rising-edge-triggered output register. They also utilize a Dual Cycle Deselect (DCD) output deselect protocol.

$\Sigma$ RAMs are implemented with high performance CMOS technology and are packaged in a 209-bump BGA.

## Pin Description Table

Symbol	Description	Type	Comments
A	Address	Input	—
ADV	Advance	Input	Active High
$\overline{Bx}$	Byte Write Enable	Input	Active Low
$\overline{W}$	Write Enable	Input	Active Low
$\overline{E1}$	Chip Enable	Input	Active Low
E2 & E3	Chip Enable	Input	Programmable Active High or Low
EP2 & EP3	Chip Enable Program Pin	Mode Input	To be tied directly to $V_{DD}$ , $V_{DDQ}$ or $V_{SS}$
CK	Clock	Input	Active High
CQ, $\overline{CQ}$	Echo Clock	Output	Three State - Deselect via E2 or E3 False
DQ	Data I/O	Input/Output	Three State
MCH	Must Connect High	Input	Active High To be tied directly to $V_{DD}$ or $V_{DDQ}$
MCL	Must Connect Low	Input	Active Low To be tied directly to $V_{SS}$
ZQ	Output Impedance Control	Mode Input	Low = Low Impedance [High Drive] High = High Impedance [Low Drive] To be tied directly to $V_{DDQ}$ or $V_{SS}$
TCK	Test Clock	Input	Active High
TDI	Test Data In	Input	—
TDO	Test Data Out	Output	—
TMS	Test Mode Select	Input	—
NC	No Connect	—	Not connected to die or any other pin
$V_{DD}$	Core Power Supply	Input	1.8 V Nominal
$V_{DDQ}$	Output Driver Power Supply	Input	1.8 V Nominal
$V_{SS}$	Ground	Input	—

## Operation Control

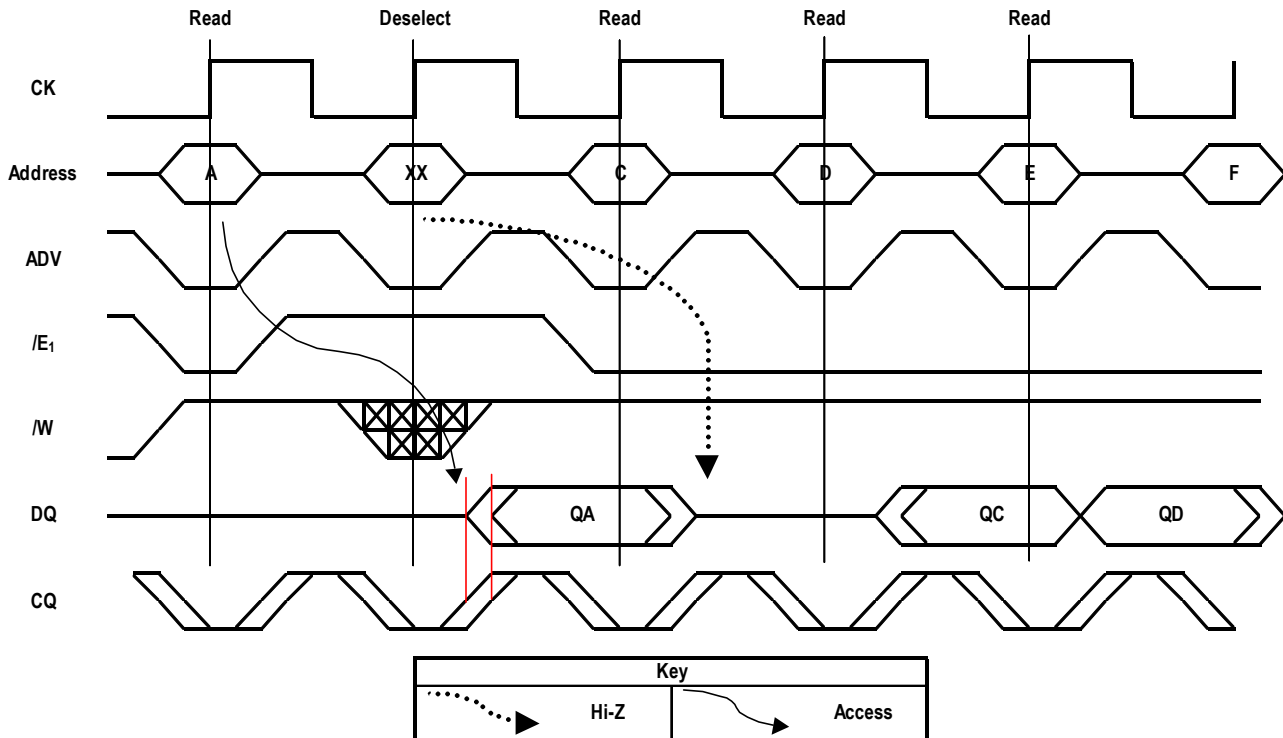

All address, data and control inputs (with the exception of EP2, EP3, ZQ, and the mode pins, L6, M6, and J6) are synchronized to rising clock edges. Data in is captured on both rising and falling edges of CK. Read and write operations must be initiated with the Advance/Load pin (ADV) held low, in order to load the new address. Device activation is accomplished by asserting all three of the Chip Enable inputs ( $\overline{E1}$ , E2, and E3). Deassertion of any one of the Enable inputs will deactivate the device. **It should be noted that ONLY deactivation of the RAM via E2 and/or E3 deactivates the Echo Clocks, CQ1–CQ2.**

## Read Operations

### Pipelined Read

Read operation is initiated when the following conditions are satisfied at the rising edge of clock: All three chip enables ( $\overline{E1}$ , E2, and E3) are active, the write enable input signal ( $\overline{W}$ ) is deasserted high, and ADV is asserted low. The address presented to the address inputs is latched into the address register and presented to the memory core and control logic. The control logic determines that a read access is in progress and allows the requested data to propagate to the input of the output register. At the next rising edge of clock the read data is allowed to propagate through the output register and onto the output pins.

### Single Data Rate Pipelined Read

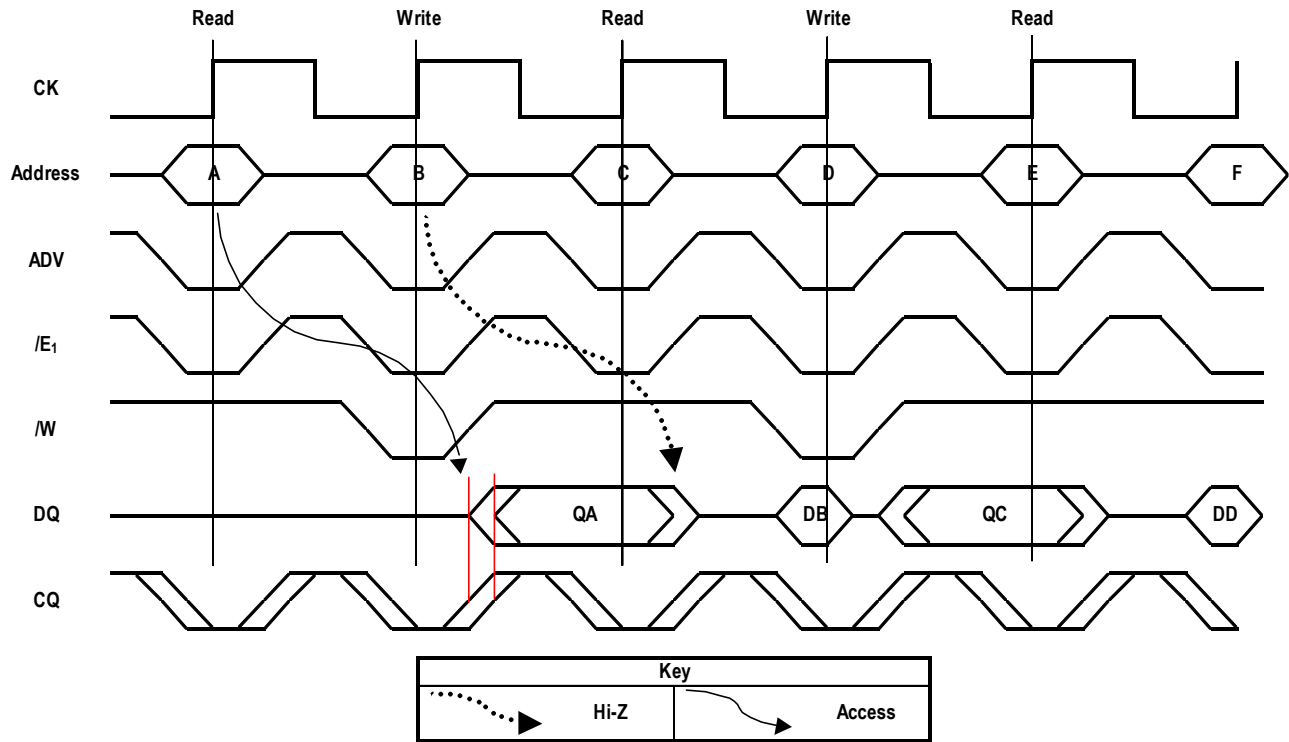

## Write Operations

Write operation occurs when the following conditions are satisfied at the rising edge of clock: All three chip enables ( $\overline{E1}$ , E2, and E3) are active, the write enable input signal ( $\overline{W}$ ) is asserted low, and ADV is asserted low.

### Double Late Write

Double Late Write means that Data In is required on the third rising edge of clock. Double Late Write is used to implement Pipeline mode NBT SRAMs.

### SigmaRAM Double Late Write with Pipelined Read

### Byte Write Control

The Byte Write Enable inputs ( $\overline{Bx}$ ) determine which bytes will be written. Any combination of Byte Write Enable control pins, including all or none, may be activated. A Write Cycle with no Byte Write inputs active is a write abort cycle.

### Example of x36 Byte Write Truth Table

Function	$\overline{W}$	$\overline{Ba}$	$\overline{Bb}$	$\overline{Bc}$	$\overline{Bd}$
Read	H	X	X	X	X
Write Byte A	L	L	H	H	H
Write Byte B	L	H	L	H	H
Write Byte C	L	H	H	L	H
Write Byte D	L	H	H	H	L
Write all Bytes	L	L	L	L	L
Write Abort	L	H	H	H	H

### Two Byte Write Control Example with Double Late Write SigmaRAM

## Special Functions

### Burst Cycles

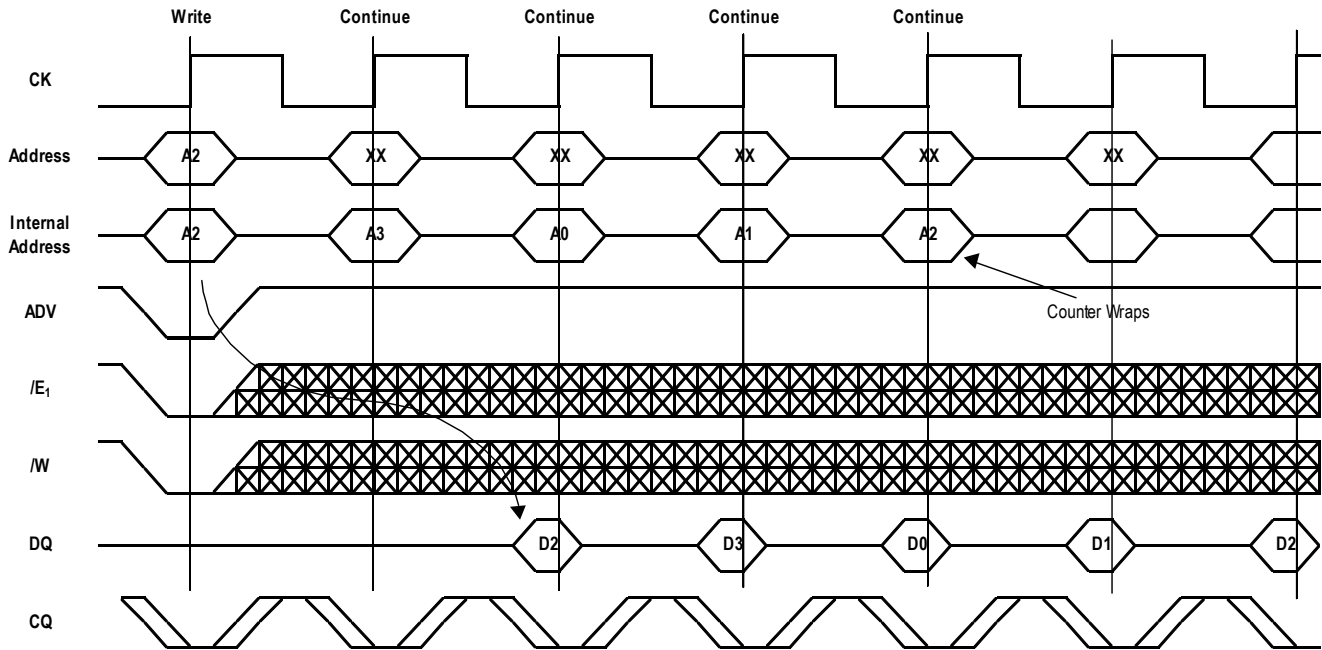

Although SRAMs can sustain 100% bus bandwidth by eliminating the bus turnaround cycle in Double Late Write mode, burst read or burst write cycles may also be performed. SRAMs provide an on-chip burst address generator that can be utilized, if desired, to simplify burst read or write implementations. The ADV control pin, when driven high, commands the SRAM to advance the internal address counter and use the counter generated address to read or write the SRAM. The starting address for the first cycle in a burst cycle series is loaded into the SRAM by driving the ADV pin low, into Load mode.

### SigmaRAM Pipelined Burst Reads with Counter Wrap-around

### SigmaRAM Double Late Write SRAM Burst Writes with Counter Wrap-around

#### Burst Order

The burst address counter wraps around to its initial state after four internal addresses (the loaded address and three more) have been accessed. SigmaRAMs always count in linear burst order.

#### Linear Burst Order

	A[1:0]			
1st address	00	01	10	11
2nd address	01	10	11	00
3rd address	10	11	00	01
4th address	11	00	01	10

Note: The burst counter wraps to initial state on the 5th rising edge of clock.

#### Echo Clock

SRAMs feature Echo Clocks, CQ1, CQ2,  $\overline{CQ1}$ , and  $\overline{CQ2}$  that track the performance of the output drivers. The Echo Clocks are delayed copies of the main RAM clock, CK. Echo Clocks are designed to track changes in output driver delays due to variance in die temperature and supply voltage. The Echo Clocks are designed to fire with the rest of the data output drivers. SigmaRAMs provide both in-phase, or true, Echo Clock outputs (CQ1 and CQ2) and inverted Echo Clock outputs ( $\overline{CQ1}$  and  $\overline{CQ2}$ ).

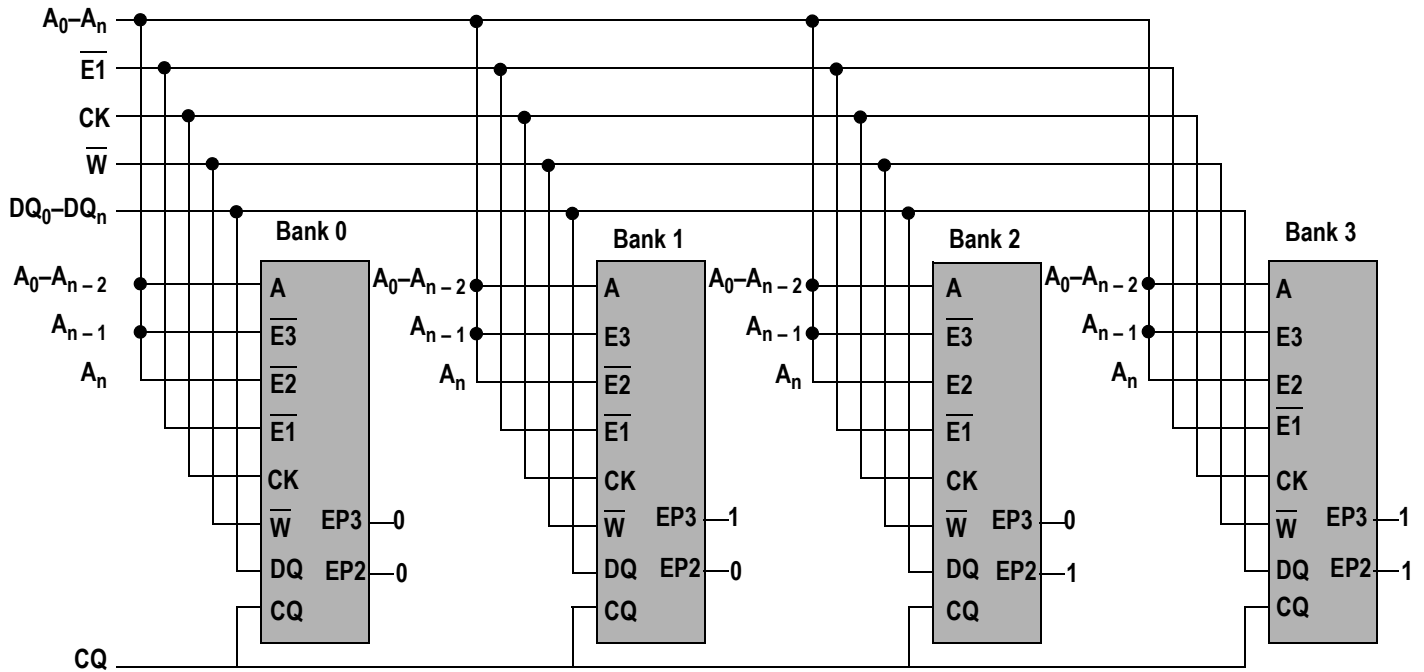

It should be noted that deselection of the RAM via E2 and E3 also deselects the Echo Clock output drivers. The deselection of Echo Clock drivers is always pipelined to the same degree as output data. **Deselection of the RAM via E1 does not deactivate the Echo Clocks.**

### Programmable Enables

SRAMs feature two user-programmable chip enable inputs, E2 and E3. The sense of the inputs, whether they function as active low or active high inputs, is determined by the state of the programming inputs, EP2 and EP3. For example, if EP2 is held at  $V_{DD}$ , E2 functions as an active high enable. If EP2 is held to  $V_{SS}$ , E2 functions as an active low chip enable input.

Programmability of E2 and E3 allows four banks of depth expansion to be accomplished with no additional logic. By programming the enable inputs of four SRAMs in binary sequence (00, 01, 10, 11) and driving the enable inputs with two address inputs, four SRAMs can be made to look like one larger RAM to the system.

### Example Four Bank Depth Expansion Schematic— $\Sigma 1 \times 1 D_p$

**Bank Enable Truth Table**

	EP2	EP3	E2	E3
<b>Bank 0</b>	$V_{SS}$	$V_{SS}$	Active Low	Active Low
<b>Bank 1</b>	$V_{SS}$	$V_{DD}$	Active Low	Active High
<b>Bank 2</b>	$V_{DD}$	$V_{SS}$	Active High	Active Low
<b>Bank 3</b>	$V_{DD}$	$V_{DD}$	Active High	Active High

### Echo Clock Control in Two Banks of SigmaRAMs

Note:  $\overline{E1}$  does not deselect the Echo Clock Outputs. Echo Clock outputs are synchronously deselected by  $\overline{E2}$  or  $\overline{E3}$  being sampled false.

It should be noted that deselection of the RAM via  $\overline{E2}$  and  $\overline{E3}$  also deselected the Echo Clock output drivers. The deselection of Echo Clock drivers is always pipelined to the same degree as output data. Deselection of the RAM via  $\overline{E1}$  does not deactivate the Echo Clocks.

In some applications it may be appropriate to pause between banks; to deselect both RAMs with  $\overline{E1}$  before resuming read operations. An  $\overline{E1}$  deselect at a bank switch will allow at least one clock to be issued from the new bank before the first read cycle in the bank. Although the following drawing illustrates a  $\overline{E1}$  read pause upon switching from Bank 1 to Bank 2, a write to Bank 2 would have the same effect, causing the RAM in Bank 2 to issue at least one clock before it is needed.

### Pipelined Read Bank Switch with $\overline{E1}$ Deselect

Note:  $\overline{E1}$  does not deselect the Echo Clock Outputs. Echo Clock outputs are synchronously deselected by  $\overline{E2}$  or  $\overline{E3}$  being sampled false.

### CMOS Output Driver Impedance Control

CMOS I/O SigmaRAMs are supplied with selectable (high or low) impedance output drivers. The ZQ pin allows selection between SRAM nominal drive strength (ZQ low) for multi-drop bus applications and low drive strength (ZQ high) point-to-point applications.

### Double Late Write, Pipelined Read Truth Table

CK	$\overline{E1}$ ( $t_n$ )	E ( $t_n$ )	ADV ( $t_n$ )	$\overline{W}$ ( $t_n$ )	B ( $t_n$ )	Previous Operation	Current Operation	DQ/CQ ( $t_n$ )	DQ/CQ ( $t_{n+1}$ )	DQ/CQ ( $t_{n+2}$ )

Notes:

1. If  $E2 = EP2$  and  $E3 = EP3$ , then  $E = "T"$  else  $E = "F"$ .
2. If one or more  $\overline{Bx} = 0$ , then  $B = "T"$  else  $B = "F"$ .
3. "1" = input "high"; "0" = input "low"; "X" = input "don't care"; "T" = input "true"; "F" = input "false".
4. "\*\*\*" indicates that the DQ input requirement / output state and CQ output state are determined by the previous operation.
5. "---" indicates that the DQ input requirement / output state and CQ output state are determined by the next operation.
6. DQs are tristated in response to Bank Deselect, Deselect, and Write commands, one full cycle after the command is sampled.
7. CQs are tristated in response to Bank Deselect commands only, one full cycle after the command is sampled.
8. Up to three (3) Continue operations may be initiated after a Read or Write operation is initiated to burst transfer up to four (4) distinct pieces of data per single external address input. If a fourth (4th) Continue operation is initiated, the internal address wraps back to the initial external (base) address.

### Common I/O State Diagram

### Current State & Next State Definition for Read/Write Control State Diagram

**Notes:**

1. The notation "X,X,X,X" controlling the state transitions above indicate the states of inputs  $\overline{E1}$ , E, ADV, and  $\overline{W}$  respectively.
2. If (E2 = EP2 and E3 = EP3) then E = "T" else E = "F".
3. "1" = input "high"; "0" = input "low"; "X" = input "don't care"; "T" = input "true"; "F" = input "false".

## Absolute Maximum Ratings

(All voltages reference to  $V_{SS}$ )

Symbol	Description	Value	Unit
$V_{DD}$	Voltage on $V_{DD}$ Pins	-0.5 to 2.5	V
$V_{DDQ}$	Voltage in $V_{DDQ}$ Pins	-0.5 to $V_{DD}$	V
$V_{I/O}$	Voltage on I/O Pins	-0.5 to $V_{DDQ} + 0.5$ ( $\leq 2.5$ V max.)	V
$V_{IN}$	Voltage on Other Input Pins	-0.5 to $V_{DDQ} + 0.5$ ( $\leq 2.5$ V max.)	V
$I_{IN}$	Input Current on Any Pin	+/-100	mA dc
$I_{OUT}$	Output Current on Any I/O Pin	+/-100	mA dc
$T_J$	Maximum Junction Temperature	125	$^{\circ}C$
$T_{STG}$	Storage Temperature	-55 to 125	$^{\circ}C$

Note:

Permanent damage to the device may occur if the Absolute Maximum Ratings are exceeded. Operation should be restricted to Recommended Operating Conditions. Exposure to conditions exceeding the Recommended Operating Conditions, for an extended period of time, may affect reliability of this component.

## Recommended Operating Conditions

### Power Supplies

Parameter	Symbol	Min.	Typ.	Max.	Unit	Notes
Supply Voltage	$V_{DD}$	1.7	1.8	1.95	V	
1.8 V I/O Supply Voltage	$V_{DDQ}$	1.7	1.8	$V_{DD}$	V	
Ambient Temperature (Commercial Range Versions)	$T_A$	0	25	70	$^{\circ}C$	1
Ambient Temperature (Industrial Range Versions)	$T_A$	-40	25	85	$^{\circ}C$	1

Note:

The part number of Industrial Temperature Range versions end the character "I". Unless otherwise noted, all performance specifications quoted are evaluated for worst case in the temperature range marked on the device.

### CMOS I/O DC Input Characteristics

Parameter	Symbol	Min.	Typ.	Max.	Unit	Notes
CMOS Input High Voltage	$V_{IH}$	$0.65 * V_{DDQ}$	—	$V_{DDQ} + 0.3$	V	1
CMOS Input Low Voltage	$V_{IL}$	-0.3	—	$0.35 * V_{DDQ}$	V	1

Note: For devices supplied with CMOS input buffers. Compatible with both 1.8 V and 1.5 V I/O drivers.

### Undershoot Measurement and Timing

### Overshoot Measurement and Timing

### Capacitance

( $T_A = 25^\circ\text{C}$ ,  $f = 1\text{ MHz}$ ,  $V_{DD} = 1.8\text{ V}$ )

Parameter	Symbol	Test conditions	Typ.	Max.	Unit
Input Capacitance	$C_{IN}$	$V_{IN} = 0\text{ V}$	4	5	pF
Output Capacitance	$C_{OUT}$	$V_{OUT} = 0\text{ V}$	6	7	pF

Note: This parameter is sample tested.

### Package Thermal Characteristics

Rating	Layer Board	Symbol	Max	Unit	Notes
Junction to Ambient (at 200 lfm)	single	$R_{\theta JA}$	TBD	$^\circ\text{C/W}$	1,2
Junction to Ambient (at 200 lfm)	four	$R_{\theta JA}$	TBD	$^\circ\text{C/W}$	1,2
Junction to Case (TOP)	n/a	$R_{\theta JC}$	TBD	$^\circ\text{C/W}$	3

Notes:

- Junction temperature is a function of SRAM power dissipation, package thermal resistance, mounting board temperature, ambient. Temperature air flow, board density, and PCB thermal resistance.
- SCMI G-38-87
- Average thermal resistance between die and top surface, MIL SPEC-883, Method 1012.1

### AC Test Conditions

Parameter	Conditions
Input high level	$V_{DDQ}$
Input low level	0 V
Max. input slew rate	2 V/ns
Input reference level	$V_{DDQ}/2$
Output reference level	$V_{DDQ}/2$

Notes:

1. Measured at 100 mV from steady state. Not 100% tested.
2. Guaranteed by design. Not 100% tested.
3. For any specific temperature and voltage tKHCZ < tKHCX1.

### Timing Parameter Key—Pipelined Read Cycle Timing

## Timing Parameter Key—Double Late Write Mode Control and Data In Timing

Note:  $t_{nVKH} = t_{EVKH}, t_{WVKH}, t_{BVKH}, \text{etc.}$  and  $t_{KHnX} = t_{KHnX}, t_{KHnX}, t_{KHnX}, \text{etc.}$

## JTAG Port Operation

### Overview

The JTAG Port on this RAM operates in a manner that is compliant with IEEE Standard 1149.1-1990, a serial boundary scan interface standard (commonly referred to as JTAG). The JTAG Port input interface levels scale with  $V_{DD}$ . The JTAG output drivers are powered by  $V_{DDQ}$ .

### Disabling the JTAG Port

It is possible to use this device without utilizing the JTAG port. The port is reset at power-up and will remain inactive unless clocked. To assure normal operation of the RAM with the JTAG Port unused, TCK, TDI, and TMS may be left floating or tied to  $V_{DDI}$ . TDO should be left unconnected.

## JTAG Pin Descriptions

Pin	Pin Name	I/O	Description
TCK	Test Clock	In	Clocks all TAP events. All inputs are captured on the rising edge of TCK and all outputs propagate from the falling edge of TCK.
TMS	Test Mode Select	In	The TMS input is sampled on the rising edge of TCK. This is the command input for the TAP controller state machine. An undriven TMS input will produce the same result as a logic one input level.
TDI	Test Data In	In	The TDI input is sampled on the rising edge of TCK. This is the input side of the serial registers placed between TDI and TDO. The register placed between TDI and TDO is determined by the state of the TAP Controller state machine and the instruction that is currently loaded in the TAP Instruction Register (refer to the TAP Controller State Diagram). An undriven TDI pin will produce the same result as a logic one input level.
TDO	Test Data Out	Out	Output that is active depending on the state of the TAP state machine. Output changes in response to the falling edge of TCK. This is the output side of the serial registers placed between TDI and TDO.

**Note:**

This device does not have a TRST (TAP Reset) pin. TRST is optional in IEEE 1149.1. The Test-Logic-Reset state is entered while TMS is held high for five rising edges of TCK. The TAP Controller is also reset automatically at power-up.

## JTAG Port Registers

### Overview

The various JTAG registers, referred to as Test Access Port or TAP Registers, are selected (one at a time) via the sequences of 1s and 0s applied to TMS as TCK is strobed. Each of the TAP registers are serial shift registers that capture serial input data on the rising edge of TCK and push serial data out on the next falling edge of TCK. When a register is selected, it is placed between the TDI and TDO pins.

### Instruction Register

The Instruction Register holds the instructions that are executed by the TAP controller when it is moved into the Run, Test/Idle, or the various data register states. Instructions are 3 bits long. The Instruction Register can be loaded when it is placed between the TDI and TDO pins. The Instruction Register is automatically preloaded with the IDCODE instruction at power-up or whenever the controller is placed in Test-Logic-Reset state.

### Bypass Register

The Bypass Register is a single-bit register that can be placed between TDI and TDO. It allows serial test data to be passed through the RAM's JTAG Port to another device in the scan chain with as little delay as possible.

### Boundary Scan Register

The Boundary Scan Register is a collection of flip flops that can be preset by the logic level found on the RAM's input or I/O pins. The flip flops are then daisy chained together so the levels found can be shifted serially out of the JTAG Port's TDO pin. The Boundary Scan Register also includes a number of place holder flip flops (always set to a logic 1). The relationship between the device pins and the bits in the Boundary Scan Register is described in the Scan Order Table following. The Boundary Scan Register, under the control of the TAP Controller, is loaded with the contents of the RAMs I/O ring when the controller is in Capture-DR state and then is placed between the TDI and TDO pins when the controller is moved to Shift-DR state. SAMPLE-Z, SAMPLE/PRELOAD and EXTEST instructions can be used to activate the Boundary Scan Register.

### JTAG TAP Block Diagram

### Identification (ID) Register

The ID Register is a 32-bit register that is loaded with a device and vendor specific 32-bit code when the controller is put in Capture-DR state with the IDCODE command loaded in the Instruction Register. The code is loaded from a 32-bit on-chip ROM. It describes various attributes of the RAM as indicated below. The register is then placed between the TDI and TDO pins when the controller is moved into Shift-DR state. Bit 0 in the register is the LSB and the first to reach TDO when shifting begins.

### ID Register Contents

	Die Revision Code				Not Used								I/O Configuration				GSI Technology JEDEC Vendor ID Code								Presence Register

### Tap Controller Instruction Set

#### Overview

There are two classes of instructions defined in the Standard 1149.1-1990; standard (Public) instructions, and device specific (Private) instructions. Some Public instructions are mandatory for 1149.1 compliance. Optional Public instructions must be implemented in prescribed ways. The TAP on this device may be used to monitor all input and I/O pads. This device will not perform INTEST but can perform the preload portion of the SAMPLE/PRELOAD command.

When the TAP controller is placed in Capture-IR state, the two least significant bits of the instruction register are loaded with 01. When the controller is moved to the Shift-IR state, the Instruction Register is placed between TDI and TDO. In this state the desired instruction is serially loaded through the TDI input (while the previous contents are shifted out at TDO). For all instructions, the TAP executes newly loaded instructions only when the controller is moved to Update-IR state. The TAP instruction set for this device is listed in the following table.

### JTAG Tap Controller State Diagram

### Instruction Descriptions

#### BYPASS

When the BYPASS instruction is loaded in the Instruction Register, the Bypass Register is placed between TDI and TDO. This occurs when the TAP controller is moved to the Shift-DR state. This allows the board level scan path to be shortened to facilitate testing of other devices in the scan path.

#### SAMPLE/PRELOAD

SAMPLE/PRELOAD is a Standard 1149.1 mandatory public instruction. When the SAMPLE / PRELOAD instruction is loaded in the Instruction Register, moving the TAP controller into the Capture-DR state loads the data in the RAMs input and I/O buffers into the Boundary Scan Register. Some Boundary Scan Register locations are not associated with an input or I/O pin, and are loaded with the default state identified in the BSDL file. Because the RAM clock is independent from the TAP Clock (TCK) it is possible for the TAP to attempt to capture the I/O ring contents while the input buffers are in transition (i.e. in a metastable state). Although allowing the TAP to sample metastable inputs will not harm the device, repeatable results cannot be expected. RAM input signals must be stabilized for long enough to meet the TAP's input data capture set-up plus hold time (t<sub>TS</sub> plus t<sub>TH</sub>). The RAM's clock inputs need not be paused for any other TAP operation except capturing

the I/O ring contents into the Boundary Scan Register. Moving the controller to Shift-DR state then places the Boundary Scan Register between the TDI and TDO pins. The Update-DR controller state transfers the contents of boundary scan cells into the holding register of each cell associated with an output pin on the RAM.

#### EXTEST

EXTEST is an IEEE 1149.1 mandatory public instruction. It is to be executed whenever the instruction register is loaded with all logic 0s. The EXTEST command does not block or override the RAM's input pins (except CK); therefore, the RAM's internal state is still determined by its input pins.

Typically, the Boundary Scan Register is loaded with the desired pattern of data with the SAMPLE/PRELOAD command. Then the EXTEST command is used to output the Boundary Scan Register's contents, in parallel, on the RAM's data output drivers on the falling edge of TCK when the controller is in the Update-IR state.

Alternately, the Boundary Scan Register may be loaded in parallel using the EXTEST command. When the EXTEST instruction is selected, the state of all the RAM's input and I/O pins, as well as the default values at Scan Register locations not associated with a pin, are sampled and transferred in parallel into the Boundary Scan Register on the rising edge of TCK in the Capture-DR state. Boundary Scan Register contents may then be shifted serially through the register using the Shift-DR command or the controller can be skipped to the Update-DR command. When the controller is placed in the Update-DR state, a RAM that has a fully compliant EXTEST function drives out the value of the Boundary Scan Register location associated with which each output pin.

#### IDCODE

The IDCODE instruction causes the ID ROM to be loaded into the ID register when the controller is in Capture-DR mode and places the ID register between the TDI and TDO pins in Shift-DR mode. The IDCODE instruction is the default instruction loaded in at power up and any time the controller is placed in the Test-Logic-Reset state.

#### SAMPLE-Z/PRELOAD

The SAMPLE-Z instruction operates exactly like SAMPLE/PRELOAD except that loading the SAMPLE-Z instruction forces all the RAM's output drivers, except TDO, to an inactive drive state (high-Z).

#### RFU

These instructions are reserved for future use.

### JTAG TAP Instruction Set Summary

Instruction	Code	Description	Notes
EXTEST	000	Places the Boundary Scan Register between TDI and TDO.	1
IDCODE	001	Preloads ID Register and places it between TDI and TDO.	1, 2
SAMPLE-Z/ PRELOAD	010	Captures I/O ring contents. Places the Boundary Scan Register between TDI and TDO. Forces all Data and Clock output drivers to High-Z.	1
Private	011	Private instruction.	1
SAMPLE/ PRELOAD	100	Captures I/O ring contents. Places the Boundary Scan Register between TDI and TDO.	1
Private	101	Private instruction.	1
Private	110	Private instruction.	1
BYPASS	111	Places Bypass Register between TDI and TDO.	1

**Notes:**

1. Instruction codes expressed in binary, MSB on left, LSB on right.
2. Default instruction automatically loaded at power-up and in Test-Logic-Reset state.

### JTAG Port Recommended Operating Conditions and DC Characteristics

Parameter	Symbol	Min.	Max.	Unit	Notes
Test Port Input High Voltage	$V_{IHT}$	$0.65 * V_{DD}$	$V_{DD}+0.3$	V	1
Test Port Input Low Voltage	$V_{ILT}$	-0.3	$0.35 * V_{DD}$	V	1
TMS, TCK and TDI Input Leakage Current	$I_{INTH}$	-2	2	uA	2
TMS, TCK and TDI Input Leakage Current	$I_{INTL}$	-50	2	uA	3
TDO Output Leakage Current	$I_{OLT}$	-2	2	uA	4
Test Port Output High Voltage	$V_{OHT}$	$V_{DD} - 100 \text{ mV}$	—	V	5, 6
Test Port Output Low Voltage	$V_{OLT}$	—	100 mV	V	7

**Notes:**

1. Input Under/overshoot voltage must be  $-1 \text{ V} < V_i < V_{DD} + 1 \text{ V}$  with a pulse width not to exceed 20% tTKC.
2.  $V_{DD} \geq V_{IN} \geq V_{IL}$
3.  $0 \text{ V} \leq V_{IN} \leq V_{IL}$
4. Output Disable,  $V_{OUT} = 0$  to  $V_{DDI}$
5. The TDO output driver is served by the  $V_{DDQ}$  supply.
6.  $I_{OH} = -100 \text{ uA}$
7.  $I_{OL} = +100 \text{ uA}$

### JTAG Port AC Test Conditions

Parameter	Conditions
Input high level	$V_{DD} - 200\text{ mV}$
Input low level	200 mV
Input slew rate	1 V/ns
Input reference level	$V_{DD}/2$
Output reference level	$V_{DDQ}/2$

**Notes:**

1. Include scope and jig capacitance.
2. Test conditions as as shown unless otherwise noted.
